

Information Security:

1. As cyberattacks get more advanced, businesses should make information security a top priority all the time, not just when it's a technical issue. This is because weak security policies can hurt finances, public trust, and long-term stability.
2. Although advanced security tools are important, human error remains one of the biggest threats to information security, which means companies must invest just as heavily in employee awareness and training as they do in software and infrastructure.
3. The growing use of artificial intelligence in information security can improve threat detection and response, but overdependence on automated systems may create new risks by reducing human oversight and making security decisions harder to question.
